Q) What is hash code in java?

A hash code in java is an integer value generated for every object by using the hashcode() method of the object class. It is used to identify an object and helps java store and retrive objects efficiently in collections like HashMap, HashSet and Hashtable.

Objects that are equal should have the same hashcode however, two different objects can sometimes have the same hashcode, which is called hash collision.

```
String s2 "Hello"
System.out.println(s.hashCode());
```
